Abstract

Time – and how to get rid of it

Where does the time go?

In this talk, we examine the various ways in which time is used during the execution of a transaction by multiple concurrent users. One of these is "lock latency". Lock latency can contribute siginificantly to the time required to perform database operations in a mutli-user environment.

We then look at how latency can be reduced to quite small intervals by careful tuning.

Time (and how to get rid of it)

Notices

- Please ask questions as we go – the only stupid questions are the ones you do not ask!

- YMMV (Your mileage may vary, transportation, meals, and accomodations not included).

"Time is what we want most,
but... what we use worst."

-- William Penn

Times you should know

thing	time
Read or write L1 cache memory	0.5 ns
Branch mispredict	5 ns
Mutex lock/unlock	100 ns
Read 1 byte from main memory	100 ns
1 microsecond	1,000 ns
Send 2K bytes over 1 Gbps network	20,000 ns
Read 1 MB sequentially from memory	250,000 ns
Round trip packet within same datacenter	500,000 ns
1 millisecond	1,000,000 ns
Disk seek	10,000,000 ns
Read 1 MB sequentially from network	10,000,000 ns
Read 1 MB sequentially from disk	30,000,000 ns
Send packet CA -> Netherlands -> CA	150,000,000 ns
1 second	1,000,000,000 ns

(from Jeff Dean @ google)

More numbers you should know.
Trust the big B !!!

Layer	Time (sec)	# of Recs	# of Ops	Time per op (nsec)	Relative
4GL to –B	0.96	100,000	203,473	4,718	1
-B to FS Cache	10.24	100,000	26,711	383,362	81
FS Cache to SAN	5.93	100,000	26,711	222,006	47
-B to SAN Cache**	11.17	100,000	26,711	418,180	89
SAN Cache to Disk	200.35	100,000	26,711	7,500,655	1590
-B to Disk	211.52	100,000	26,711	7,918,834	1678

*** Used concurrent IO to eliminate FS cache effects*

actual measurements made by Tom Bascom on customer AIX system

Test environment: ATM

- Same as the one in Secret Bunker 2017
  - but database is only 12 GB instead of 100
- Simulates ATM withdrawal transaction
- 150 concurrent users
  - execute as many transactions as possible in given time
  - result reported as "transactions per second".
- Highly update intensive
  - fetch 3 rows
  - update 3 rows
  - create 1 row with 1 index entry

our test machine, bunker15

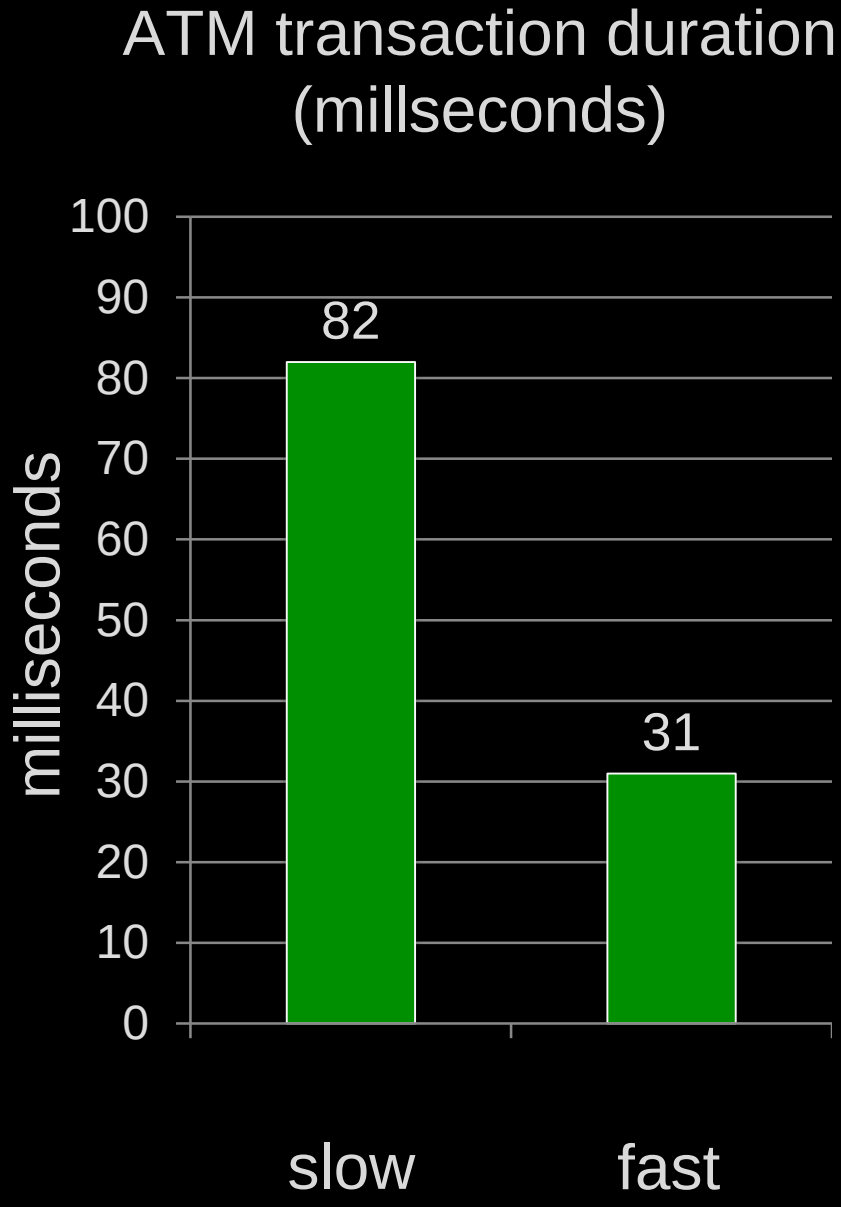
- 4 quad-core 2.4 GHz intel processors
- 64 GB memory
- 16 x 300 GB 10,000 rpm sas drives in RAID 10
- Centos 6 Linux (2.6.32-504.12.2.el6.x86_64)
- OpenEdge 11.7
- ATM 7

initial configuration

OE 11.7
database size 12 GB
150 self-serving clients

-db atm
-maxAreas 50
-omsize 4096
-n 200
-spin 5000
-L 10240
-B 64000
-bibufs 64

let's run some tests



ATM transaction duration (millseconds)

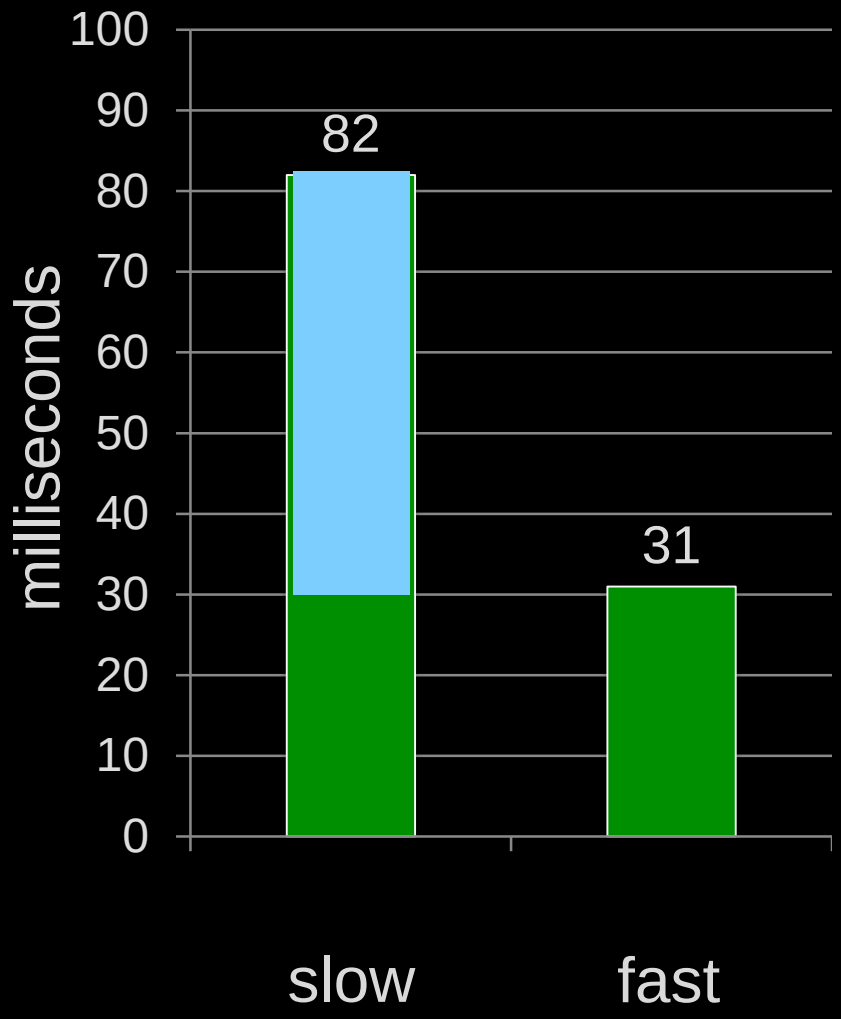
ATM transaction duration

what is going on for 51 of 82 milliseconds ?



nothing at all.

for more than half the time.

nothing at all.

for more than half the time.

what is causing it?

can we eliminate it?

The ATM transaction does the following (for 150 users):

0) execute 4GL code

1) fetch records from db, reading from cache

2) generate BI notes

3) update and create records

4) create index entries

5) write to disk

6) get and release various kinds of locks

kinds of locks:

0) record locks

1) MTX lock

2) TXE lock

3) data buffer locks

4) bi buffer locks

5) latches

Latches are typically held for very short times.

maybe as little as 100 nanoseconds

on modern computers

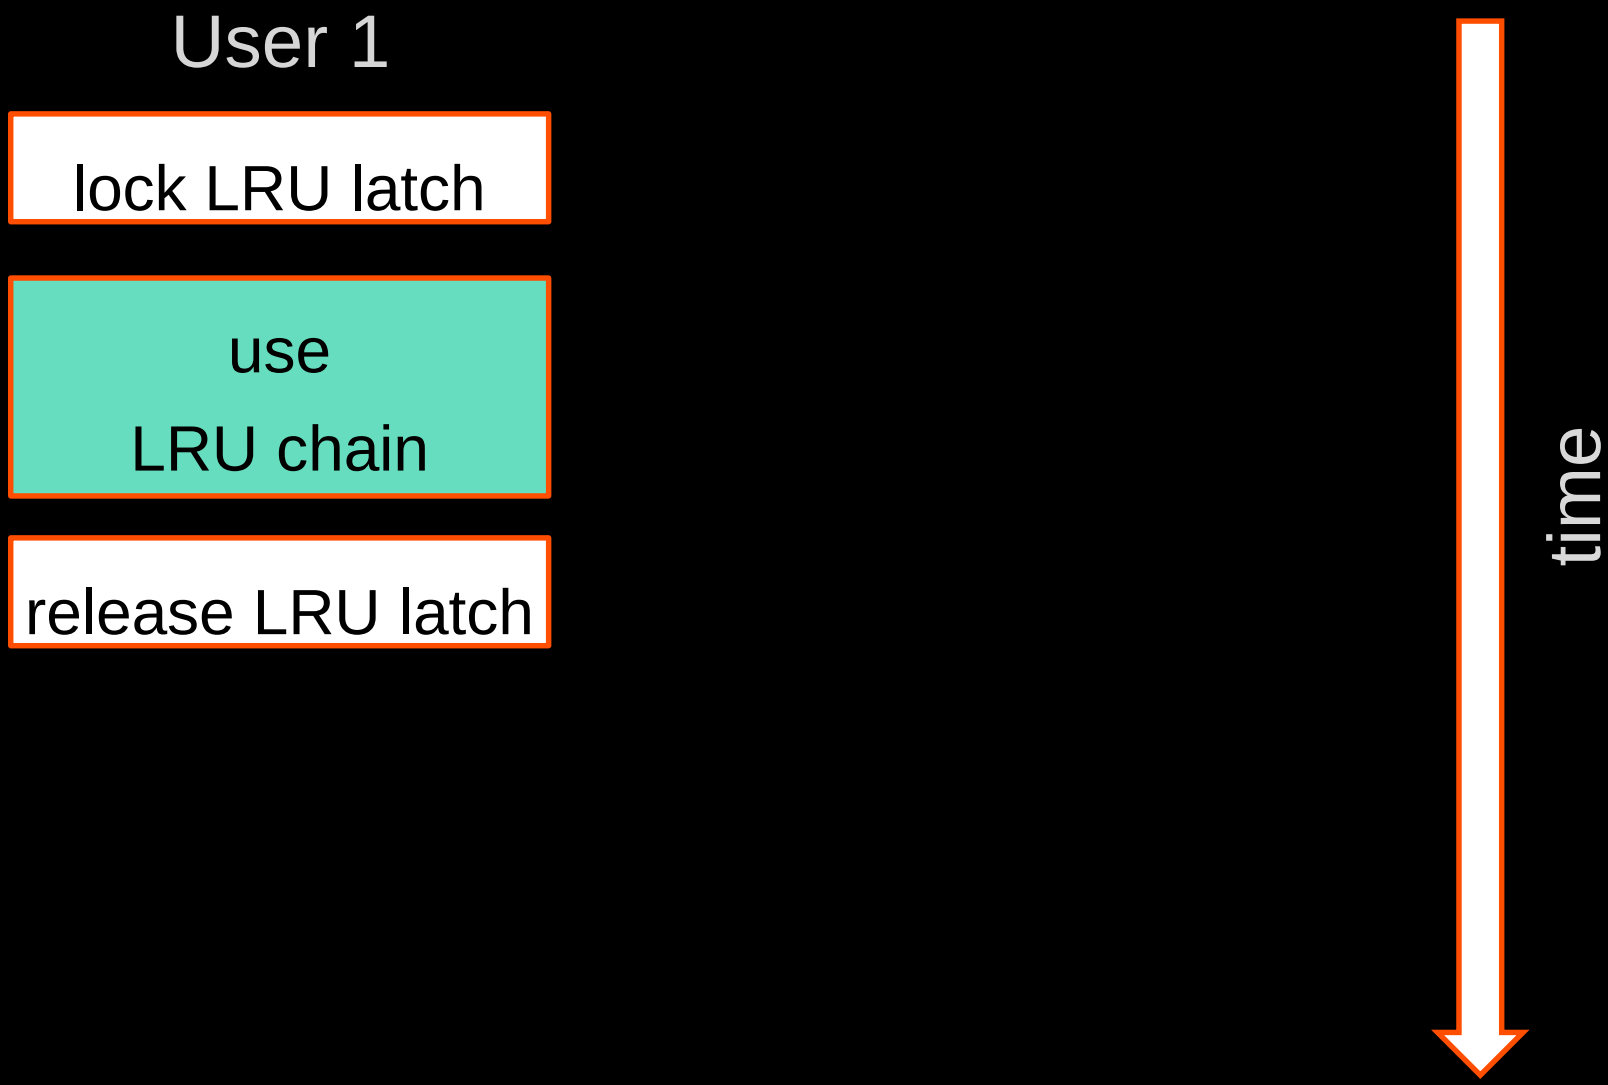
btw: with 2.4 GHz processor, 100 nsec is 239 clocks

Lock latency:

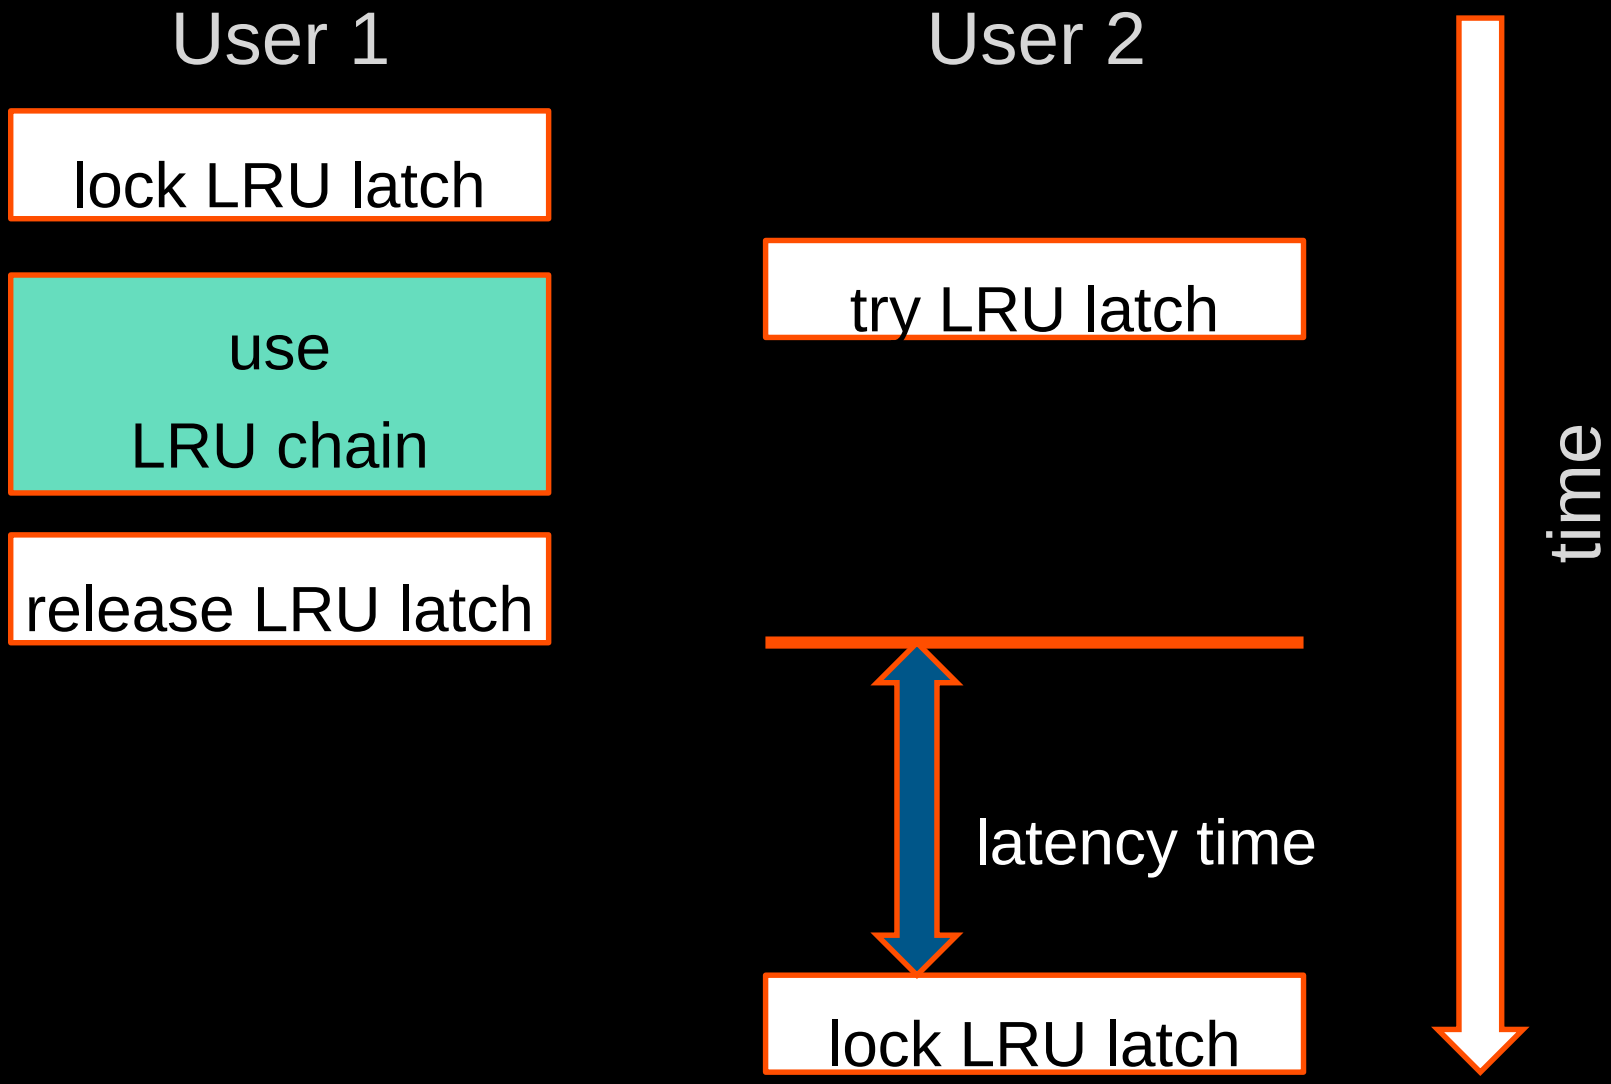
time when lock holder releases lock

until waiting acquirer has locked it.

No useful work done.



User 1
lock LRU latch
use
LRU chain
release LRU latch
time



User 1
User 2
lock LRU latch
use
LRU chain
release LRU latch
try LRU latch
latency time
lock LRU latch
time

Spinlock latches:

test and set
spin and test
take a nap
spin and test
nap longer
spin and test
nap even longer

-spin

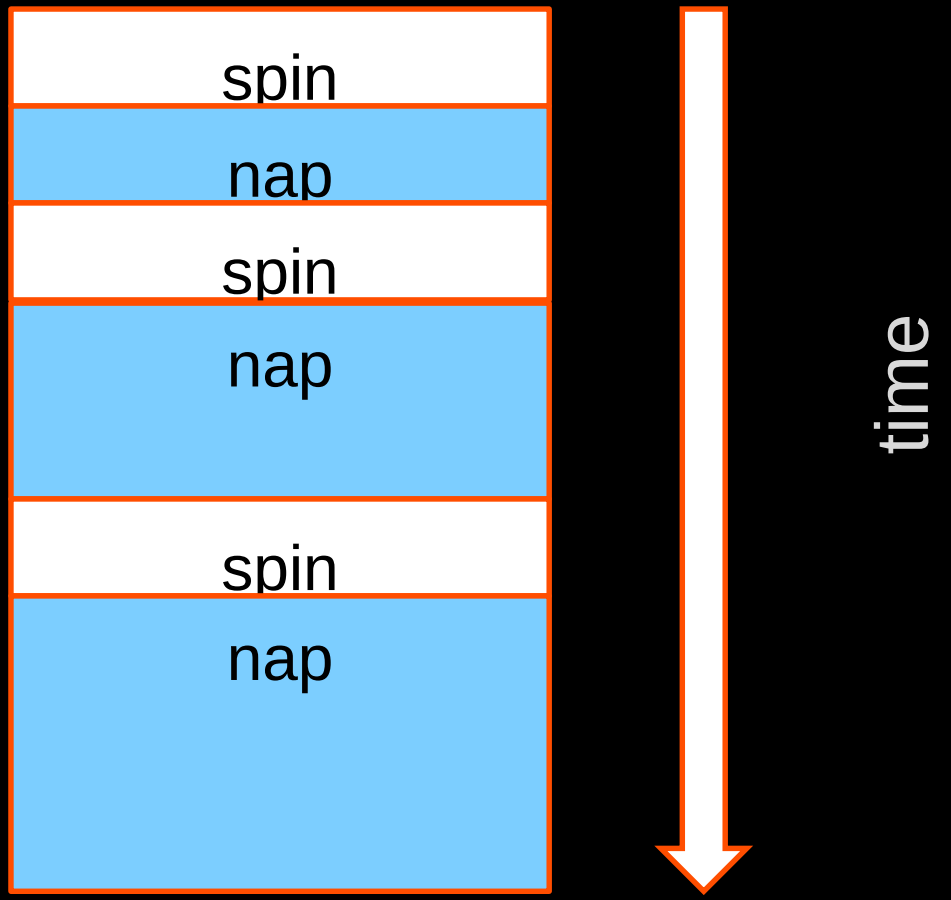
-nap

-napmax

-spin limits duration of white boxes

-nap sets minimum duration of blue boxes

-napmax sets maximum duration of blue boxes

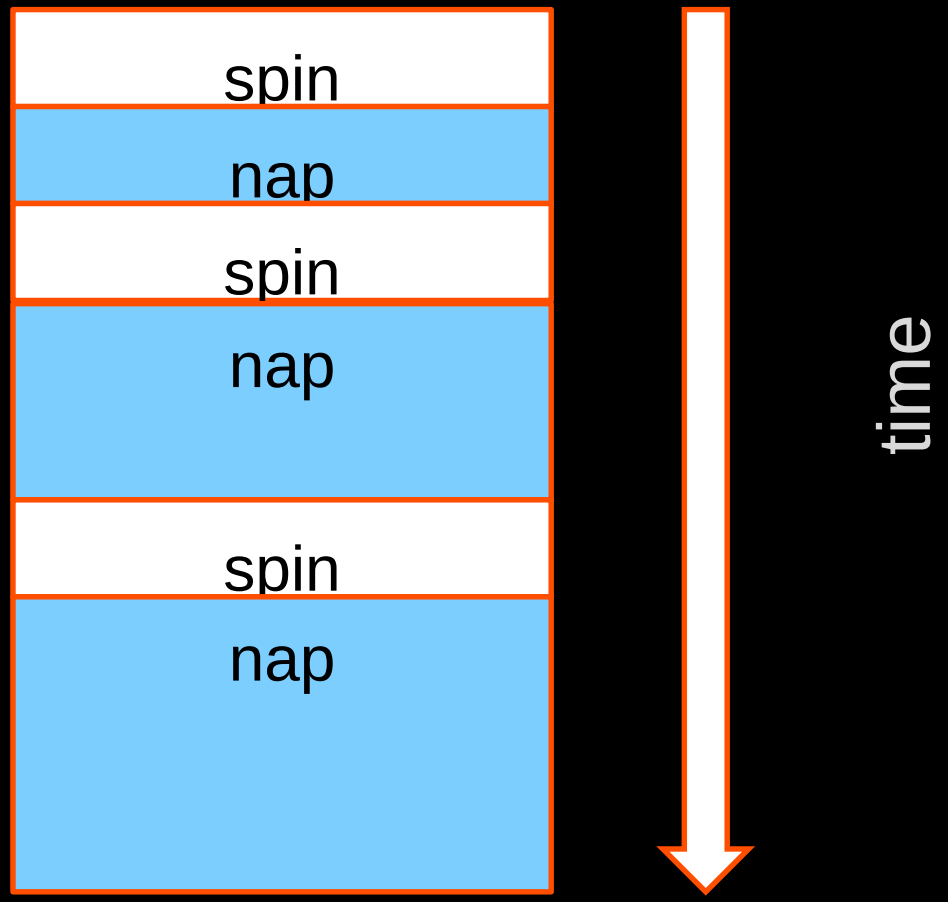


Tuning

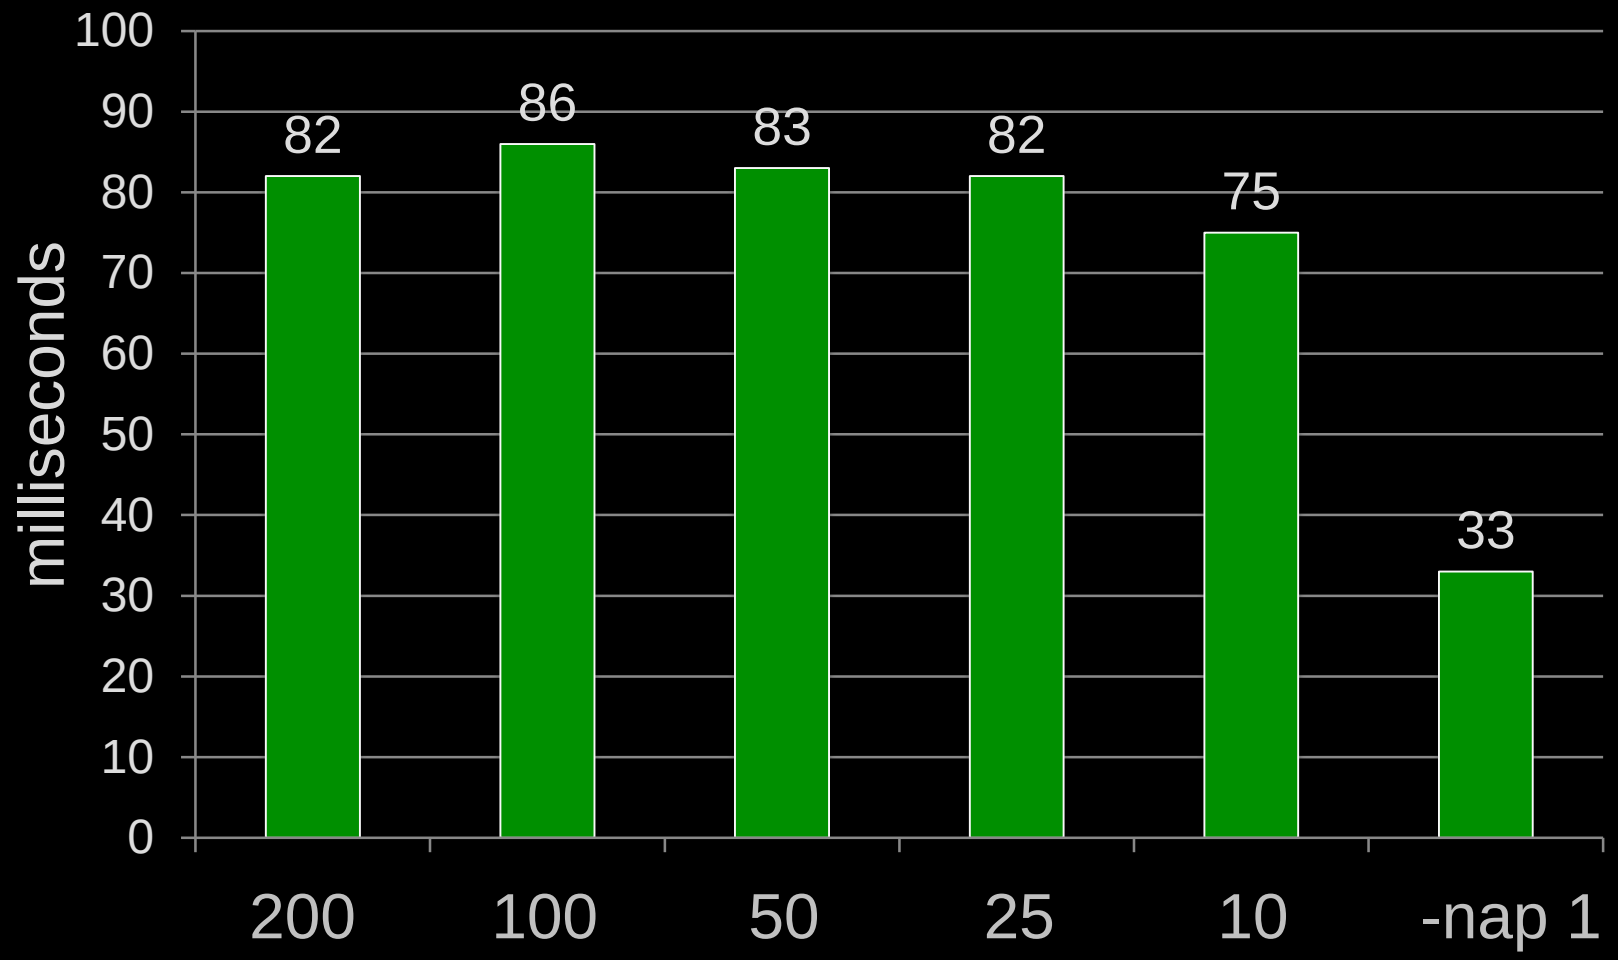
-napmax

(max size of

blue boxes)



-spin 5,000 vary -napmax



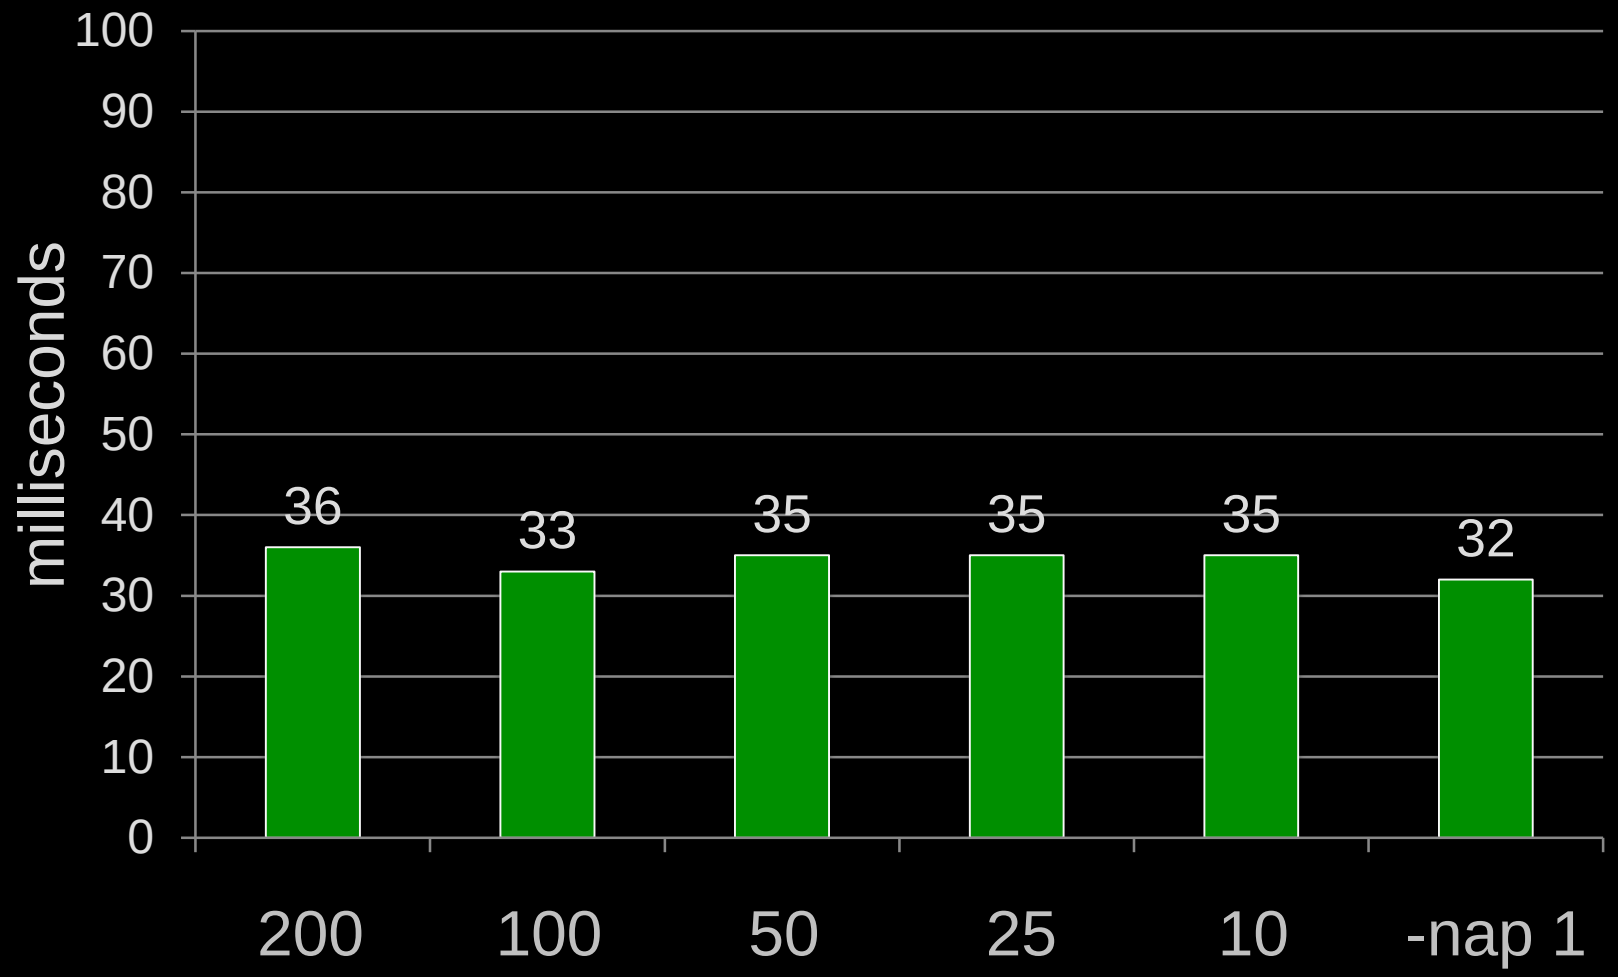
Change -spin to 50,000

Tune –napmax again

Does this mean everyone should set -napmax to 10?

NO!

-spin 50,000: vary -napmax



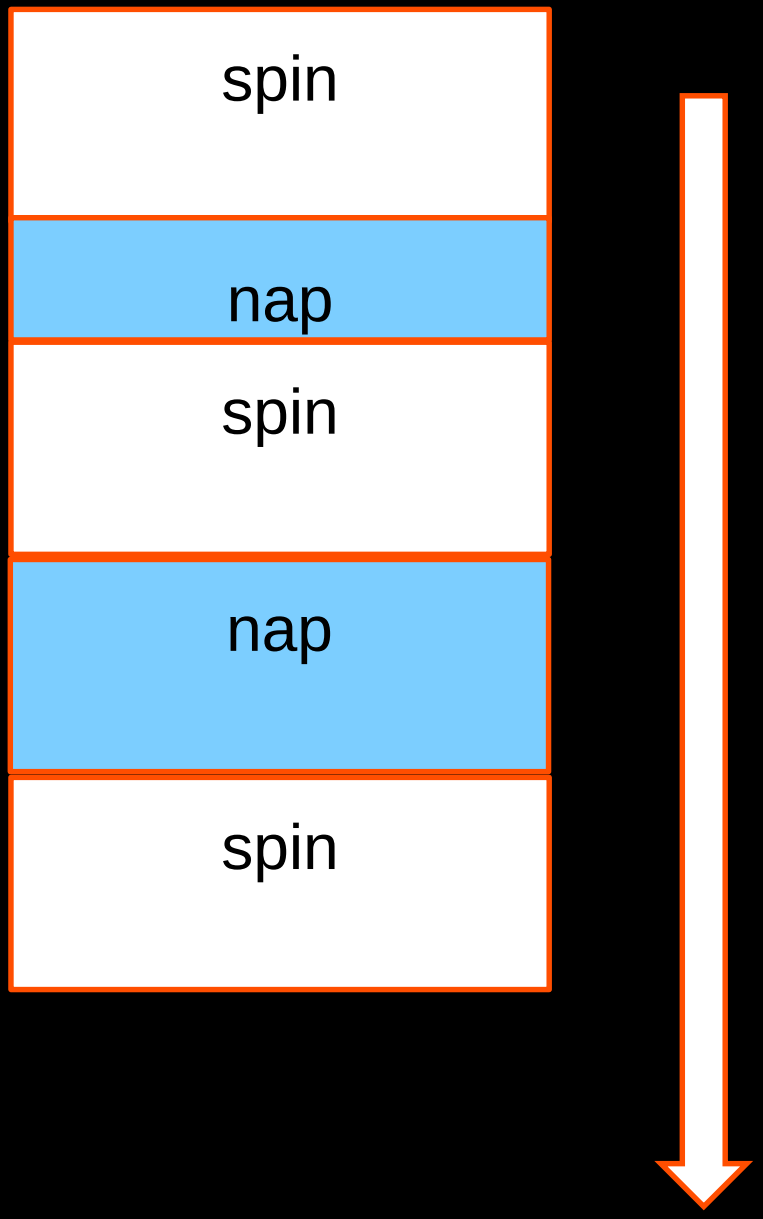
Tuning

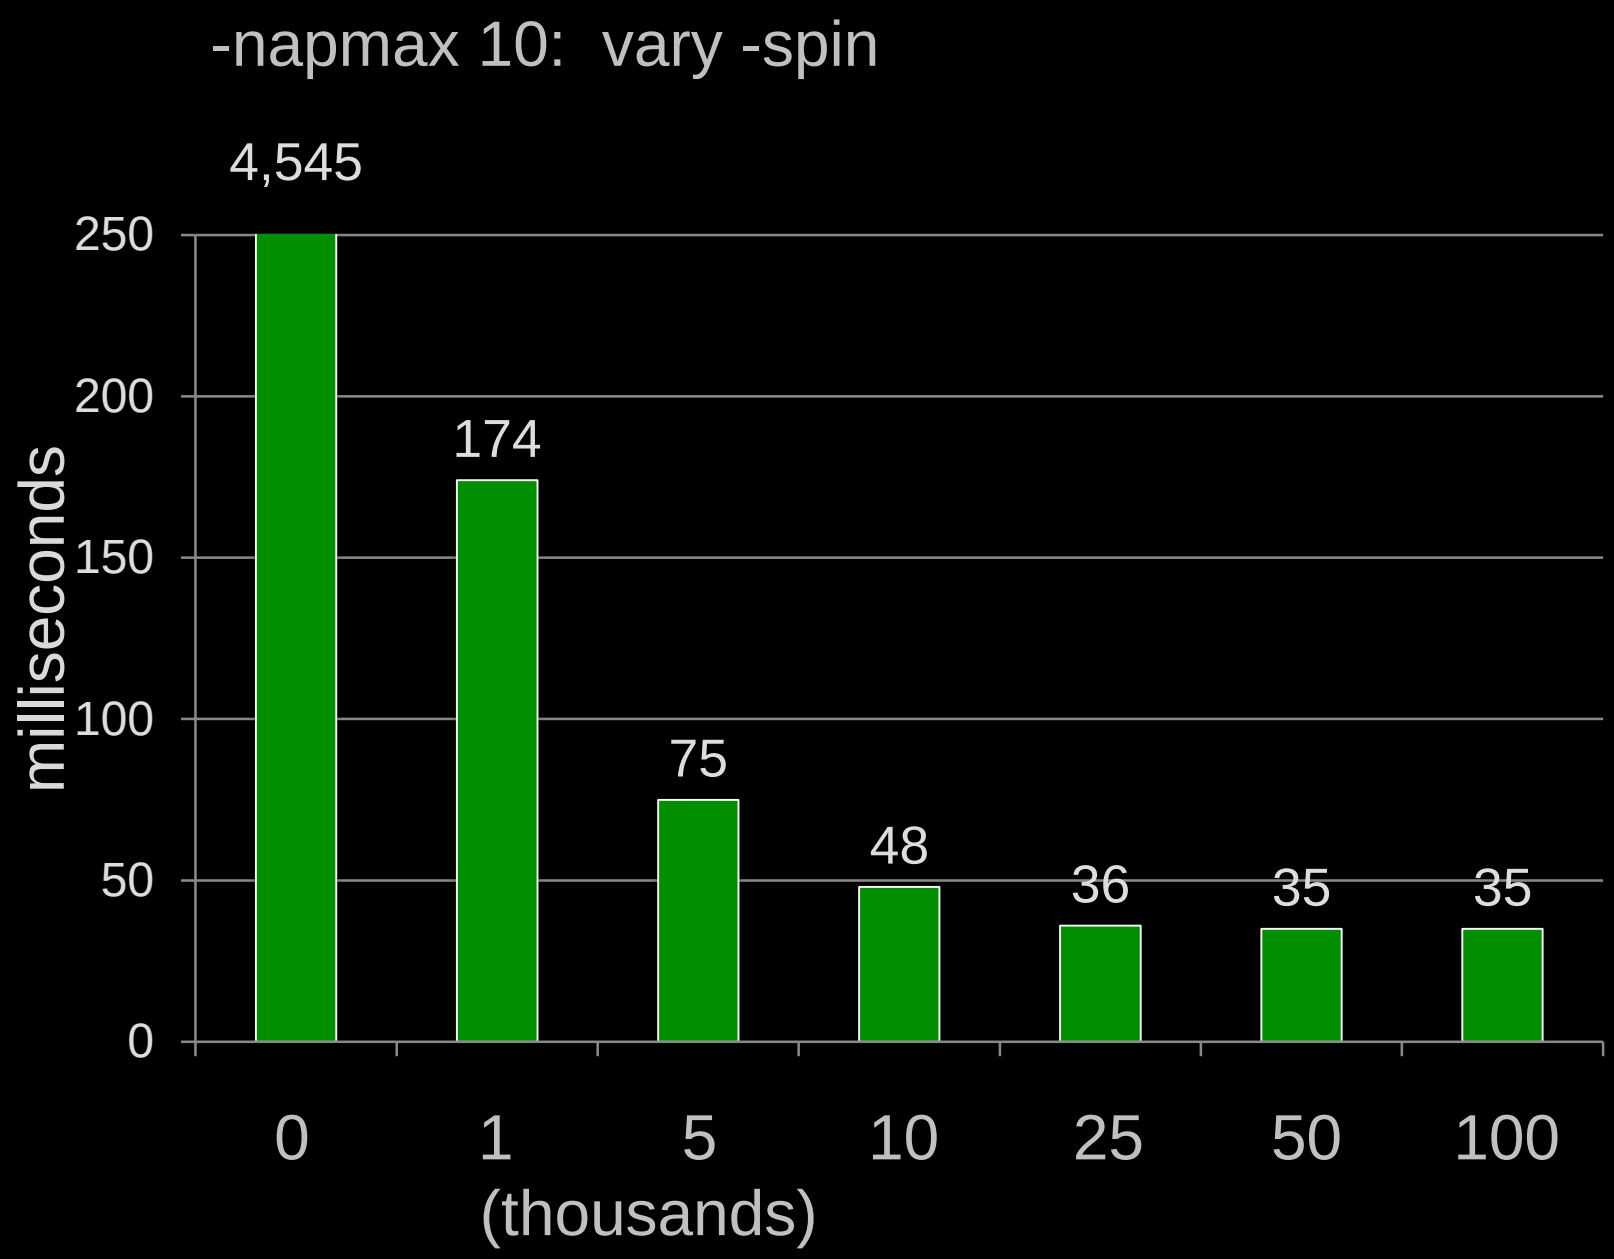
-spin

(white boxes)

Spin longer

before naps





-napmax 10: vary -spin

(thousands)

When you are in a white box,
you learn latch is free almost instantly

When you are in a blue box,
you cant tell when latch is free

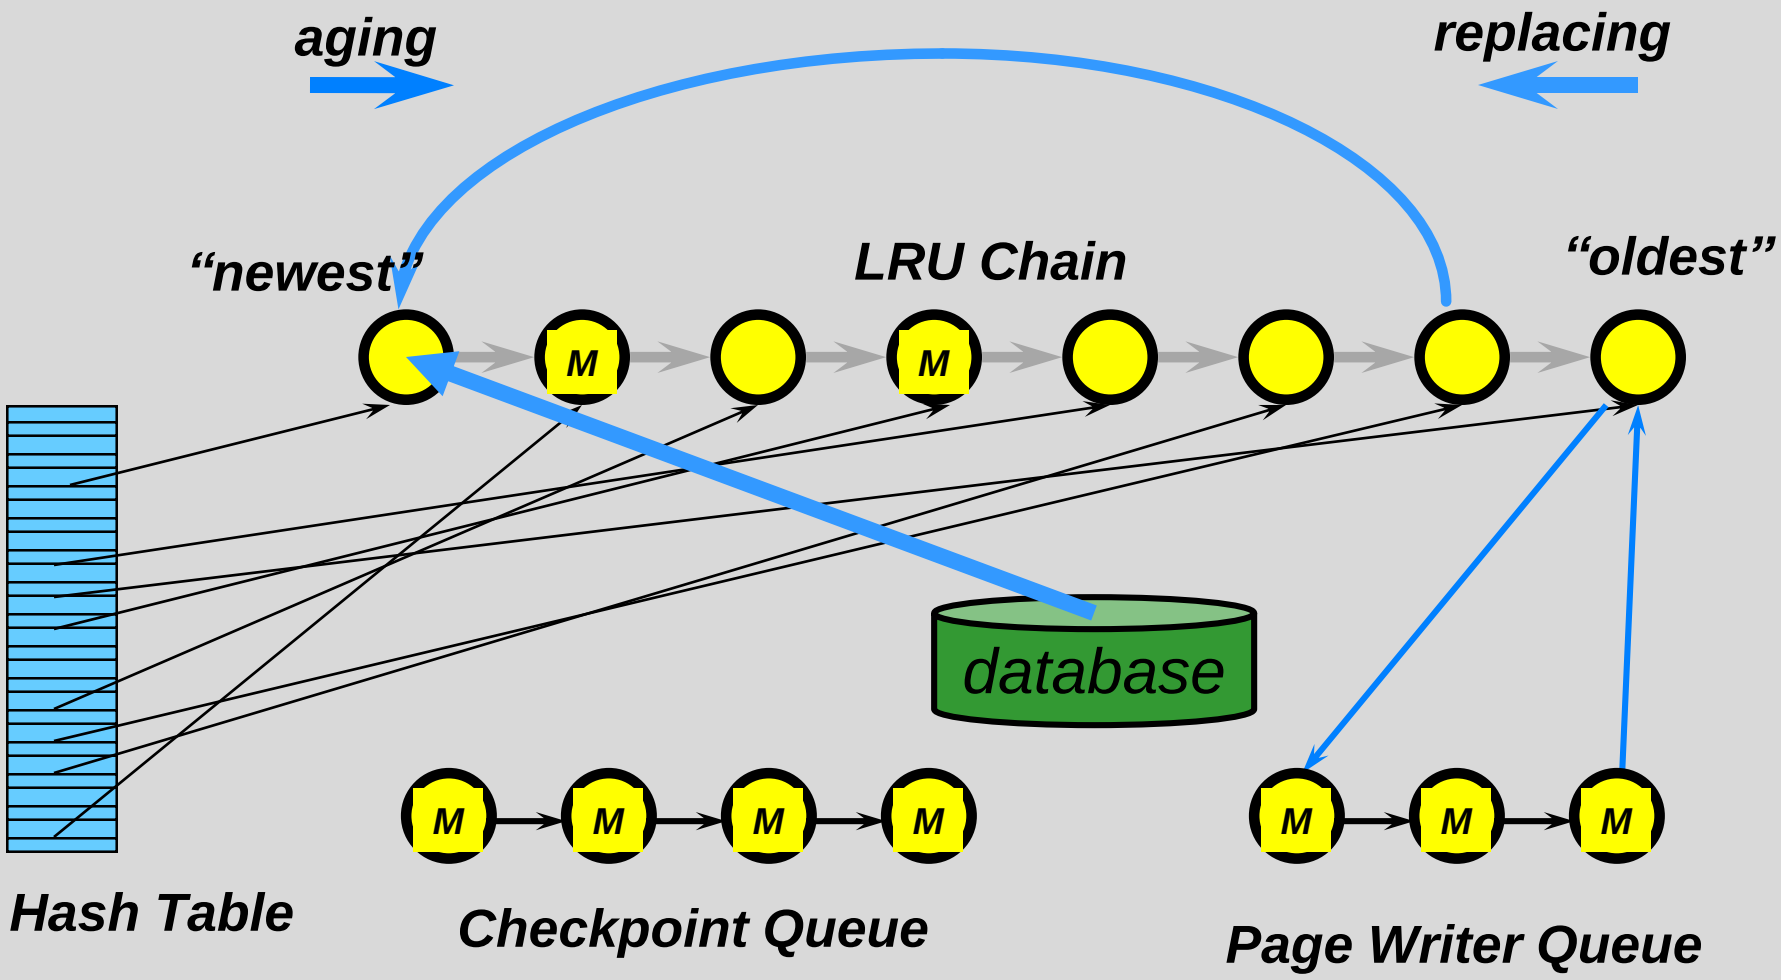
Longer nap times => higher latch latency

Higher spin => lower latch latency

Higher contention => higher latch latency

LRU chain maintenance

Buffer Pool LRU Chain



Every buffer access causes an LRU chain update

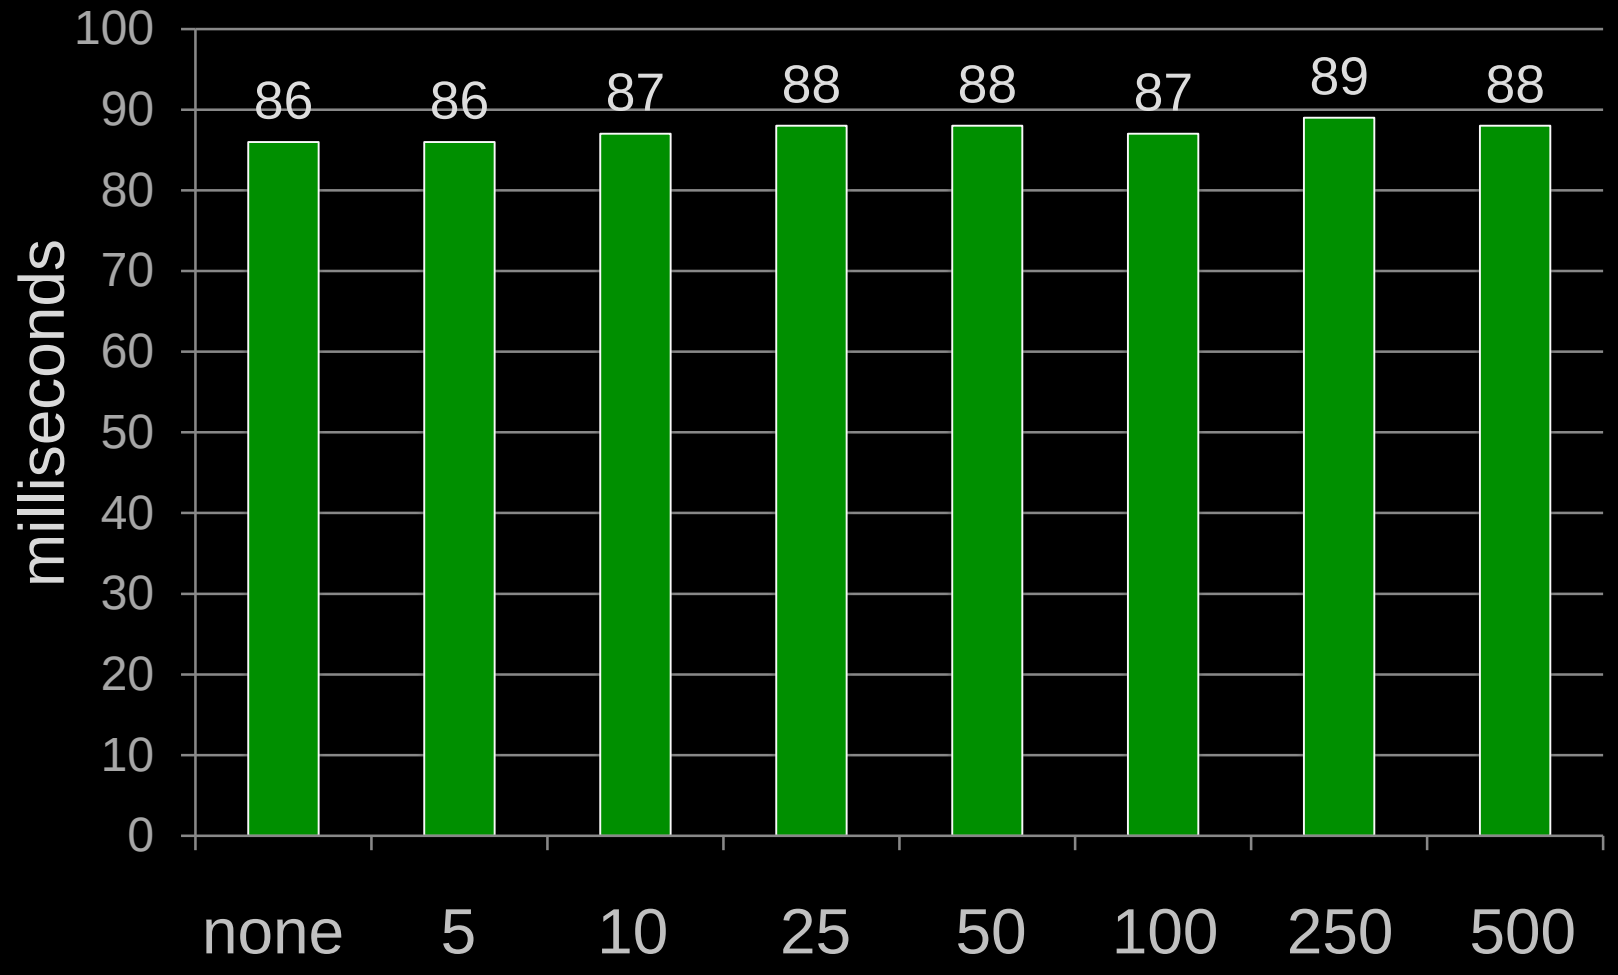
Can we reduce LRU chain overhead

and associated latch contention?

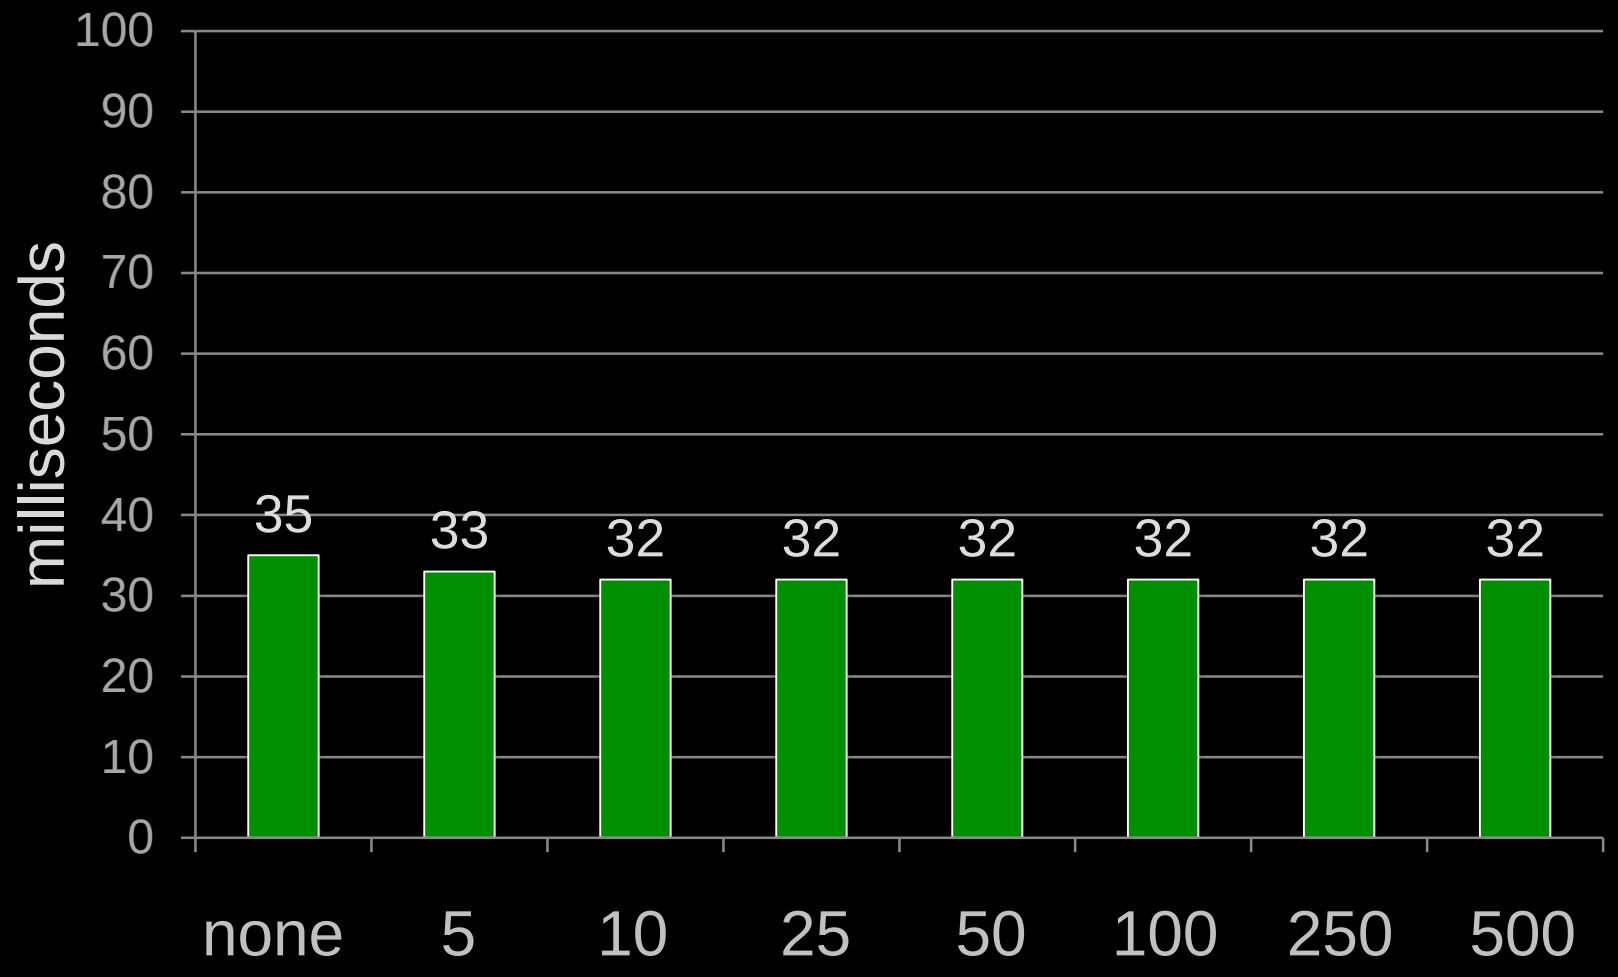
Tuning –lruskips

Using latches less

napmax 250 (default), spin 5,000: vary lruskips

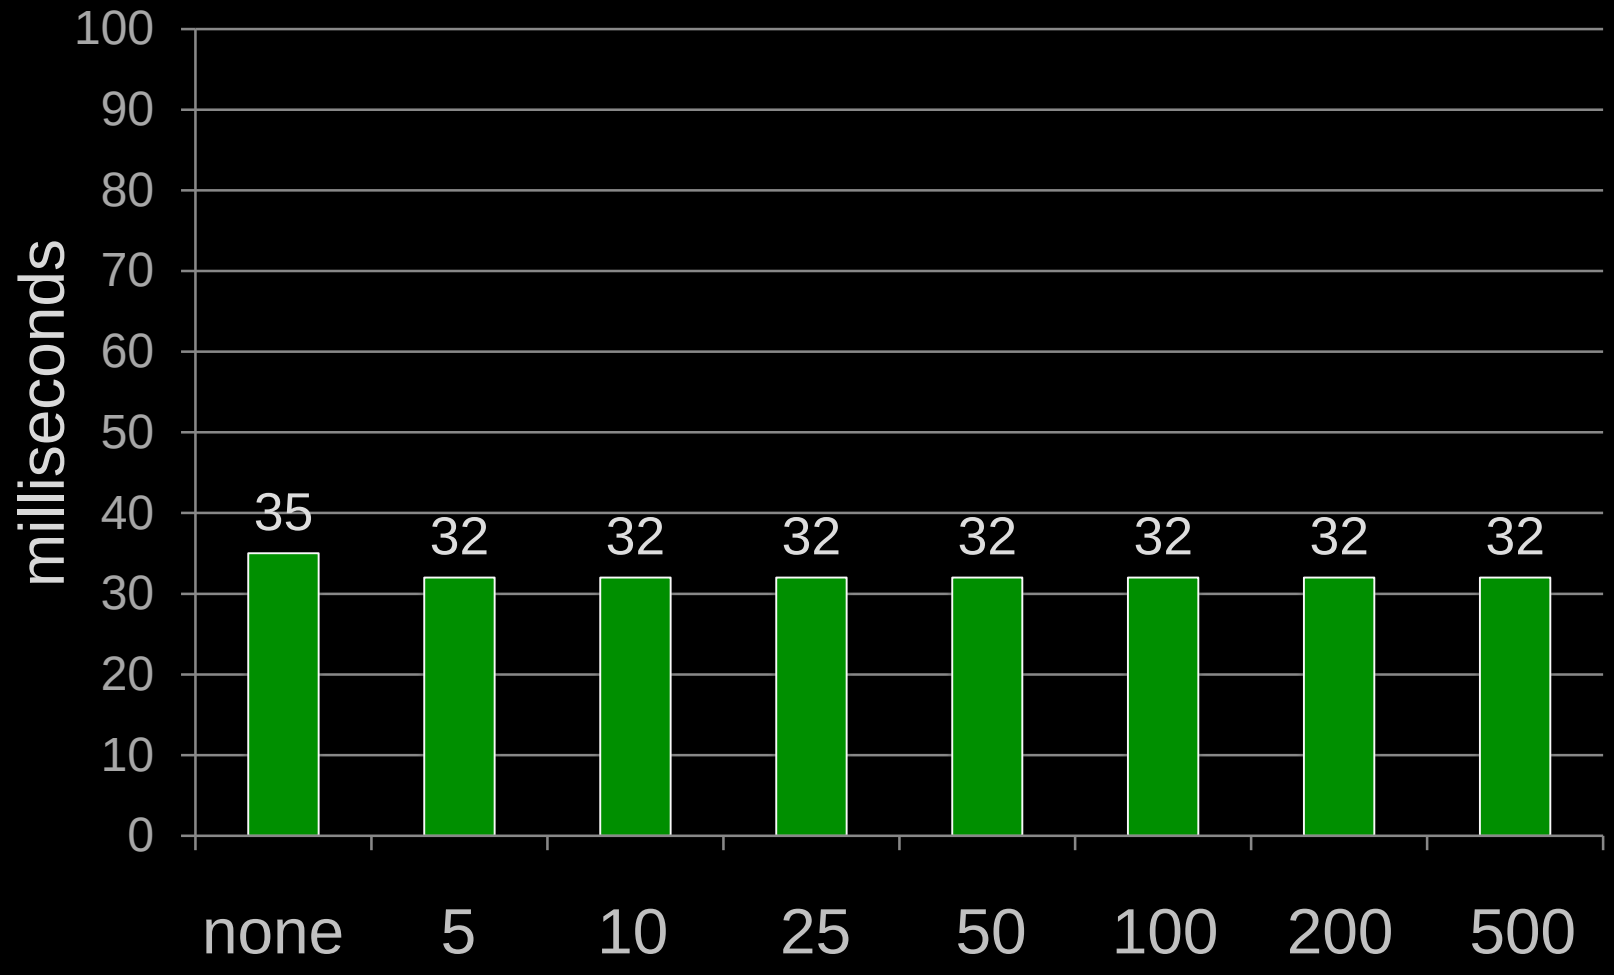


napmax 250 (default), spin 50,000: vary lruskips



napmax 10, spin 50,000: vary lruskips

napmax 10, spin 50,000: vary lruskips

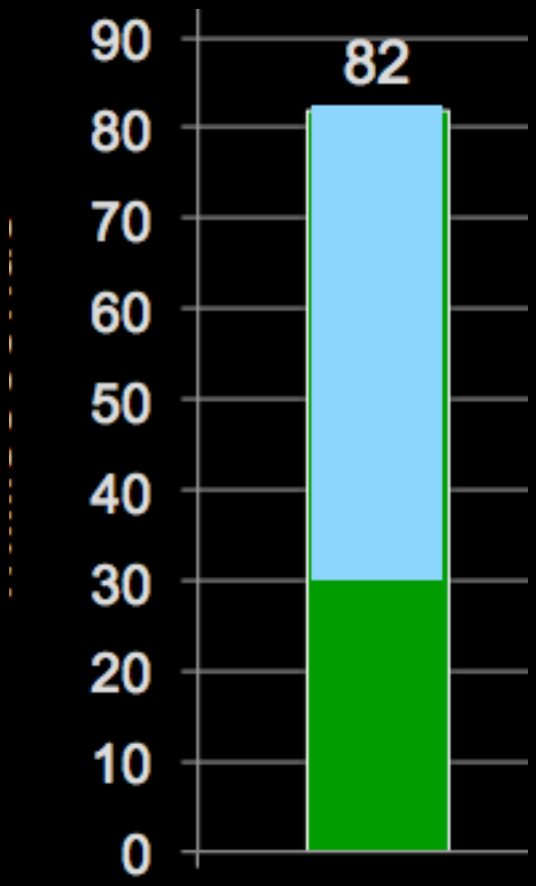


"Experience is a brutal teacher because
she gives the test first and the lesson afterwards."

-- Vernon Sanders Law

By tuning, we got rid of 51 milliseconds of time.

wasted time.



What do we learn from all this?

0) small changes have small effects

1) sometimes big changes have small effects

2) proper use of -spin has yuuge effects

3) -spin should be higher than we thought

4) -napmax should probably be low
(but watch out!)

5) spin, napmax, lruskips interact

6) lruskips 25 to 100 seems sufficient
